Cloud Computing and Extensive Margins of Exports - Evidence for Manufacturing Firms from 27 EU Countries*

Joachim Wagner

Leuphana University Lüneburg and Kiel Centre for Globalization

[This version: February 8, 2024]

Abstract

The use of cloud computing by firms can be expected to go hand in hand with higher productivity, more innovations, and lower costs, and, therefore, should be positively related to export activities. Empirical evidence on the link between cloud computing and exports, however, is missing. This paper uses firm level data for manufacturing enterprises from the 27 member countries of the European Union taken from the Flash Eurobarometer 486 survey conducted in February – May 2020 to investigate this link. Applying standard parametric econometric models and a new machine-learning estimator, Kernel-Regularized Least Squares (KRLS), we find that firms which use cloud computing do more often export, do more often export to various destinations all over the world, and do export to more different destinations. The estimated cloud computing premium for extensive margins of exports is statistically highly significant after controlling for firm size, firm age, patents, and country. Furthermore, the size of this premium can be considered to be large. Extensive margins of exports and the use of cloud computing are positively related.

JEL classification: D22, F14

Keywords: Cloud computing, exports, firm level data, Flash Eurobarometer 486, kernel-regularized least squares (KRLS)

1. Motivation

Digital technologies like artificial intelligence, cloud computing, the use of robots to automate processes, or big data analytics, are more and more widely applied by innovative firms. However, comprehensive empirical evidence on the links between the use of digital technologies and various dimensions of firm performance seems to be lacking. A case in point is the role of these technologies for export activities of firms. In their comprehensive discussion of artificial intelligence (AI) and international trade Goldfarb and Trefler (2018, p. 1) state that “even to the extent that progress has been made in understanding the impact of AI, we remain largely uninformed about its international dimensions. This is to our great loss.”¹

This note attempts to contribute to closing one of these gaps by looking at differences in extensive margins of exports between firms that use or do not use cloud computing. To the best of my knowledge it is the first empirical study to do so.²

We expect these differences to be positive for firms that use cloud computing for three reasons:

First, Chen and Volpe Martincus (2022, p. 16) report that cloud computing has significantly boosted firm productivity over the last decade. Evidence in line with this is found in DeStefano, Kneller and Timmis (2024) and Haucap, Fritz and Thorwarth (2022). According to a large empirical literature that uses firm level data from many different countries productivity and export activities in firms are positively related (Ferencz, López-González and García 2022, p. 12; see Wagner 2007 for a survey of the empirical literature).

Second, Haucap, Fritz and Thorwarth (2022, p.6) report evidence that a large share of companies stated in a survey that they were able to develop new innovative products and

¹ See Ferencz, López-González and García (2022), Goldfarb and Trefler (2018) and Meltzer (2018) for a discussion of various aspects of the relations between artificial intelligence and international trade and Wagner (2023) for a study on the use of big data analytics and exports of firms from 27 EU countries.

² See the comprehensive recent survey of the economic literature on digitalization and globalization by Chen and Volpe Martincus (2022) – no existing evidence on the effects of cloud computing on trade (or foreign direct investment) is reported (see table 2 on p. 19). Exports are not looked at in the important study on cloud computing and firm growth by DeStefano, Kneller and Timmis (2024).

services through the use of cloud computing. It can be considered as a stylized fact that innovations are positively related to export activities of firms from developed industrial countries.

Third, Chen and Volpe Martincus (2022, p. 16) point out that cloud computing lowers the need for businesses to make upfront investments in hardware and software and maintain IT infrastructure. By making IT services available on-demand on a pay-as-you-go basis, cloud computing transforms IT input costs from large, centralized sunk costs into variable costs (Chen and Volpe Martincus (2022, p.1). This can be expected to lead to a cost advantage for firms that use cloud computing and to an increase in their international competitiveness. Furthermore, we know that international firm activities, including exports, tend to go hand in hand with presence of the firms on the web (see Wagner (2022)). If cloud computing lowers the costs of setting up and maintaining web presence, it lowers the costs of exporting, too. All this can be expected to increase export activities.

This note is the first empirical study that looks at differences in exports between manufacturing enterprises from 27 member countries of the European Union that use or do not use cloud computing. In doing so it adds to our understanding of the role of cloud computing in exports by presenting evidence for firms from a large number of countries. Furthermore, we report results for various extensive margins of exports beyond participation in exporting by looking at exports to seven distinct areas of the world market for goods. It should be pointed out that a new machine-learning estimator, Kernel-Regularized Least Squares (KRLS), is applied as a robustness check besides standard parametric econometric models.

To anticipate the most important result we find that firms which use cloud computing do more often export, do more often export to various destinations all over the world, and do export to more different destinations. The estimated cloud

computing premium for exports is statistically highly significant after controlling for firm size, firm age, patents, and country. Furthermore, the size of this premium can be considered to be large. The take-home message, therefore, is that extensive margins of exports and the use of cloud computing are positively related.

The rest of the paper is organized as follows. Section 2 introduces the data used and discusses the export activities that are looked at. Section 3 reports results from the econometric investigation. Section 4 concludes.

2. Data and discussion of variables

The firm level data used in this study are taken from the Flash Eurobarometer 486 survey conducted in February – May 2020. Note that while the data were collected at the start of the COVID-19 pandemic, information on export activities relates to the year 2019, the year before the pandemic. We use data for firms from the 27 member states of the European Union in 2020 (i.e., firms from the UK are no longer included in the sample). The sample covers 2,355 firms from manufacturing industries (included in NACE section C); the numbers of firms by country are reported in the appendix table.

In the survey firms were asked in question Q23_2 whether they introduced cloud computing, i.e. the use of remote servers via the internet for storage of files or processing of data. Firms that answered in the affirmative are classified as users of cloud computing. Descriptive evidence is reported in Table 1, showing a share of 44.8 percent of firms using cloud computing.

In the empirical study we look at various measures of export activity of firms:³

First, firms were asked in question Q11_1 whether they exported any goods (or not) in 2019. Firms are classified as exporters or non-exporters based thereon.

³ Note that all measures looked at here refer to extensive margins of exports; information on intensive margins (share of exports in total sales) are not available in the data used.

Descriptive evidence is reported in Table 1, showing a share of 64.5 percent of exporters.

[Table 1 near here]

Second, firms were asked in questions Q11_2 to Q11_8 whether they exported goods in 2019 to the following destinations: Other EU countries; other European countries outside the EU (including Russia); North America; Latin America; China; other countries from Asia and the Pacific; countries from the Middle East and Africa. Descriptive evidence is reported in Table 1, showing that 61.8 percent of firms exported to countries from the EU, while 29.2 percent exported to other European countries. The other destinations follow with shares between some 10 percent and about 16 percent. Exporters to each destination are investigated separately.

Third, from the evidence reported for exports to the seven destinations mentioned for each exporting firm the number of different destinations exported to is calculated. The share of firms by number of export destinations is reported in Table 2. Not surprisingly, most exporters serve one or two destinations only, but there are quite some firms that export to more (or even all) destinations.

[Table 2 near here]

In the empirical investigation of the link between the use of cloud computing and exports we control for three firm characteristics that are known to be positively linked with exports: firm age (measured in years, based on the answer given to question Q1), firm size (measured as the number of employees – excluding the owners - at the time of the survey; see question Q2A), and whether the firms has a patent or a patent application pending (see question Q9_6).⁴ Descriptive statistics are again reported in Table 1.

⁴ Given that these variables are included as control variables only, we do not discuss them in detail here. Suffice it to say that numerous empirical studies show a positive link between these firm characteristics and export performance.

Furthermore, in the empirical investigations the country of origin of the firms is controlled for by including a full set of country dummy variables.

3. Testing for cloud computing premium in export activities

To test for the difference in the types of export activities listed in section 2 between firms that do and do not use cloud computing, and to document the size of these differences, an empirical approach is applied that modifies a standard approach used in hundreds of empirical investigations on the differences between exporters and non-exporters that has been introduced by Bernard and Jensen (1995, 1999). Studies of this type use data for firms to compute the so-called exporter premium, defined as the ceteris paribus percentage difference of a firm characteristic - e.g. labour productivity - between exporters and non-exporters.

Here we look at differences between firms that do and that do not use cloud computing (instead of differences between exporters and non-exporters) and are interested in the existence and size of a cloud computing premium in export activities (instead of an exporter premium in various forms of firm performance like productivity).⁵ For export activities that are measured by dummy variables (the decision to export or not, and the decision to export to one of the seven export destinations listed in section 2) the empirical model in (1) is estimated by Probit.

$$(1) \text{Indicator}_i = a + \beta \text{Cloud computing}_i + c \text{Control}_i + e_i$$

where i is the index of the firm, Indicator is a dummy variable for the use or not of a type of export activity, Cloud computing is a dummy variable for the use of cloud computing by the firm (1 if the firm uses it, 0 else), Control is a vector of control

⁵ For studies that use the identical empirical approach to investigate the relation between the use of big data analytics or robots and exports, see Wagner (2023, 2024a).

variables (that consists of measures of firm age, firm size, and patents, and dummy variables for countries), and e is an error term. The cloud computing premium is computed as the estimated average marginal effects of the cloud computing dummy variable.

For the number of export destinations, (1) becomes (2)

$$(2) \text{Number}_i = a + \beta \text{Cloud computing}_i + c \text{Control}_i + e_i$$

where i is the index of the firm, number is the number of export destinations, Cloud computing is a dummy variable for the use of cloud computing by the firm (1 if the firm uses it, 0 else), Control is a vector of control variables (that consists of measures of firm age, firm size, and patents, and dummy variables for countries), and e is an error term. The model (2) is estimated by OLS. The cloud computing premium is the estimated coefficient β ; it shows the average difference between firms that use and do not use cloud computing, controlling for firm age, firm size, patents, and country of origin of the firm.

3.1 Results from standard parametric models

In a first step, the empirical models outlined above are estimated using standard parametric econometric models with Probit or OLS. Results are reported in the first columns of tables 3 - 5.

The big picture that is shown is crystal clear: Firms that use cloud computing are more often exporters. Furthermore, firms with cloud computing do more often export to any of the seven different destinations looked at here, and do export to a larger number of destinations. Each estimated cloud computing premium is statistically highly significant *ceteris paribus* after controlling for firm age, firm size,

patents, and country of origin of the firms.⁶ Furthermore, the size of this premium can be considered to be large – the estimated marginal effects reported in the first columns of Table 3 and Table 4 are in the order of magnitude of five to eleven percent, and from Table 5 we see that the average difference in the number of destinations exported to is 0.455 in favour of firms that use cloud computing (with an average value of 1.544 destinations for all firms).

[Tables 3 – 5 near here]

3.2 Results from Kernel-Regularized Least Squares (KRLS) models

In the standard parametric models used in section 3.1 the firm characteristics that explain the export margins enter the empirical model in linear form. This functional form which is used in hundreds of empirical studies for margins of exports, however, is rather restrictive. If any non-linear relationships (like quadratic terms or higher order polynomials, or interaction terms) do matter and if they are ignored in the specification of the empirical model this leads to biased results. Researchers, however, can never be sure that all possible relevant non-linear relationships are taken care of in their chosen specifications. In a robustness check of the results from the standard parametric models, therefore, this note uses the Kernel-Regularized Least Squares (KRLS) estimator to deal with this issue. KRLS is a machine learning method that learns the functional form from the data. It has been introduced in Hainmueller and Hazlett (2014) and Ferwerda, Hainmueller and Hazlett (2017), and used to estimate empirical models for margins of trade for the first time in Wagner (2024)⁷.

⁶ Note that all control variables have the expected positive sign and all are highly significant statistically.

⁷ The only other application of KRLS in economics is Minviel and Ben Bouheni (2022), a study of the impact of research and development on economic growth with macro data.

While a comprehensive discussion of the Kernel-Regularized Least Squares (KRLS) estimator is far beyond the scope of this applied note, a short outline of some of the important features and characteristics might help to understand why this estimator can be considered as an extremely helpful addition to the box of tools of empirical trade economists (see Wagner (2024b)). For any details the reader is referred to the original papers by Hainmueller and Hazlett (2014) and Fernwerda, Hainmueller and Hazlett (2017).

The main contribution of the KRLS estimator is that it allows the researcher to estimate regression-type models without making any assumption regarding the functional form (or doing a specification search to find the best fitting functional form). As detailed in Hainmueller and Hazlett (2014) the method constructs a flexible hypothesis space using kernels as radial basis functions and then finds the best-fitting surface in this space by minimizing a complexity-penalized least squares problem. Ferwerda, Hainmueller and Hazlett (2017) point out that the KRLS method can be thought of in the “similarity-based view” in two stages. In the first stage, it fits functions using kernels, based on the assumption that there is useful information embedded in how similar a given observation is to other observations in the dataset. In the second stage, it utilizes regularization, which gives preference to simpler functions (see Ferwerda, Hainmueller and Hazlett (2017), p.3).

KRLS works well both with continuous outcomes and with binary outcomes. It is easy to apply in Stata using the `krls` program provided in Ferwerda, Hainmueller and Hazlett (2017). Instead of doing a tedious specification search that does not guarantee a successful result, users simply pass the outcome variable and the matrix of covariates to the KRLS estimator which then learns the target function from the data. As shown in Hainmueller and Hazlett (2014), the KRLS estimator has desirable statistical properties, including unbiasedness, consistency, and asymptotic normality

under mild regularity conditions. An additional advantage of KRLS is that it provides closed-form estimates of the pointwise derivatives that characterize the marginal effect of each covariate at each data point in the covariate space (see Ferwerda, Hainmueller and Hazlett (2017), p. 11). These estimates can be used to examine the heterogeneity of the marginal effects.

Therefore, KRLS is suitable to estimate empirical models when the correct functional form is not known for sure – which is usually the case because we do not know which polynomials or interaction terms matter for correctly modelling the relation between the covariates and the outcome variable.

Results for an application of KRLS to the models for margins of exports are reported in the second to fifth columns of tables 3 - 5.

The big picture that is shown is again crystal clear, and it is identical to the one shown by the standard parametric models: Firms that use cloud computing are more often exporters, do more often export to any of the different destinations, and do export to a larger number of destinations. Each estimated premium is statistically highly significant *ceteris paribus* after controlling for firm age, firm size, patents, and country of origin of the firms.⁸ Furthermore, the size of this premium can again be considered to be large, although the estimated average marginal effects tend to be somewhat smaller here than in the standard parametric models. The difference in the size of the average marginal effects can be explained by the fact that the parametric model in column 1 imposes a restrictive functional form in the shape of the estimated relationships, while KRLS estimated this relationship without imposing a functional form.

An additional advantage of KRLS compared to the parametric models used in the original estimation is that it provides closed-form estimates of the pointwise

⁸ Note that again all control variables have the expected positive sign and all are highly significant statistically.

derivatives that characterize the marginal effect of each covariate at each data point in the covariate space (see Ferwerda, Hainmueller and Hazlett (2017), p. 11). The last three columns of tables 3 - 5 report the marginal effects estimated by KRLS at the 1st quartile, at the median, and at the 3rd quartile. We can clearly see the heterogeneity in the marginal effects. The estimated marginal effects differ widely over the quartiles and tend to increase for all variables considered here. This shows the nonlinearity and heterogeneity of the relationship between the covariates and the share of exports in total sales.

4. Concluding remarks

This study finds that manufacturing firms from 27 EU member countries that use cloud computing are more often exporters than firms that do not use cloud computing. Furthermore, firms with cloud computing do more often export to any of the seven different destinations looked at here, and do export to a larger number of destinations. The estimated premium is large for all types of export activities looked at here.

Does this study imply that in order to be successful in export markets, firms should use cloud computing? Or that using cloud computing will help the firms to be successful as an exporter? This is an open question (that is asked the same way when the exporter premium is discussed; see Wagner (2007)) because we do not know whether this premium is due to self-selection of exporting firms into the use of cloud computing, or whether it is the effect of using cloud computing. This issue cannot be investigated with the cross-section data at hand. To answer this important question longitudinal data for firms are needed that cover several years and that include a sufficiently large number of firms that switch the status between using cloud

or not over time (in both directions). The jury is still out to find a generally accepted answer.

Cloud computing (Dummy; 1 = yes)	0.0802 (0.000)	0.0659 (0.000)	0.0398	0.0541	0.0965
Firm age (years)	0.0012 (0.000)	0.00116 (0.000)	0.00047	0.00099	0.0017
Firm size (Number of employees)	0.000094 (0.000)	0.00032 (0.000)	0.00026	0.00031	0.00037
Patent (Dummy; 1 = yes)	0.1443 (0.000)	0.1435 (0.000)	0.1060	0.1424	0.1816

Number of cases	2,355	2,355			

Note: Probit reports average marginal effects from a model estimated by ML Probit. KRLS reports average marginal effects and marginal effects at the 25th, 50th and 75th percentile estimated by kernel-based regularized least squares. P-values are reported in parentheses. All models include a set of country dummies. For details, see text.

Table 5: Empirical results, Part III: Number of export destinations

Method	OLS Regression coefficient	KRLS Average marginal effect	P25	P50	P75
Cloud computing (Dummy; 1 = yes)	0.4547 (0.000)	0.3454 (0,000)	0.2108	0.3479	0.4453
Firm age (years)	0.0109 (0.000)	0.0088 (0.000)	0.0061	0.0088	0.0120
Firm size (Number of employees)	0.00081 (0.002)	0.0012 (0.000)	0.0010	.0012	0.0014
Patent (Dummy; 1 = yes)	0.9657 (0.000)	0.8233 (0.000)	0.6172	0.8747	1.02
26 country dummies	included	included			
Number of cases	1,520	1,520			

Note: OLS reports the estimated regression coefficients from a linear model. KRLS reports average marginal effects and marginal effects at the 25th, 50th and 75th percentile estimated by kernel-based regularized least squares. P-values are reported in parentheses. For details, see text.

Appendix: Number of Firms by Country

Country	Number of Firms	Percent
Austria	86	3.65
Belgium	81	3.44
Bulgaria	97	4.12
Cyprus	33	1.40
Czech Republic	94	3.99
Germany	74	3.14
Denmark	75	3.18
Estonia	99	4.20
Spain	137	5.82
Finland	88	3.74
France	101	4.29
Greece	111	4.71
Croatia	136	5.77
Hungary	117	4.97
Ireland	30	1.27
Italy	149	6.33
Lithuania	64	2.72
Luxembourg	25	1.06
Latvia	75	3.18
Malta	21	0.89
Netherlands	55	2.34
Poland	101	4.29
Portugal	93	3.95
Romania	102	4.33
Sweden	75	3.18
Slovenia	130	5.52
Slovakia	106	4.50
Total	2,355	100.0
